

MediKiosk — Feature Roadmap & Future Vision

A short reference for evolving MediKiosk into an AI-powered clinical intake and patient case-tracking platform.

1. Core Vision

MediKiosk should reduce the clinical history-taking and fragmented-record problem in high-volume OPDs by collecting history before consultation, digitizing useful previous documents, organizing information chronologically, and presenting a physician-ready view.

2. Planned Features

Feature	Purpose
Patient Registration + QR	Unique Patient ID; QR contains only the Patient ID; email ID + QR.
Patient Search / Scan	Find an existing patient using Patient ID or QR.
Automatic Medical Timeline	Chronologically organize consultations, investigations, prescriptions, reports and referrals.
Medical Document Intelligence	Upload/scan a document, capture useful clinical information, verify it, and attach it to the timeline.
Smart Case Summary	Later: concise physician-readable summary from history and documents.
Doctor-to-Doctor Handover	Later: concise previous-doctor context for continuing the case.
Pending Actions	Later: track follow-ups, investigations and referrals.
Consent & Access History	Later: record consent and case-access activity.
Multilingual UI	English + Hindi + Tamil initially; expand later.
Voice AI Assistant	Future: conversational history-taking and adaptive questions.
Red-Flag Detection	Future: identify potential urgent symptoms and alert triage staff; not autonomous diagnosis.
AYUSH Mode	Future: AYUSH-specific history fields such as Dashavidha Pariksha.

3. Current Plan

Now: Build the Automatic Medical Timeline using the existing patient/consultation data. It should update automatically whenever a new consultation, investigation, document, prescription or referral is saved.

Next: Build a simple Medical Document Intelligence module. Avoid advanced OCR initially. Upload a prescription/report/discharge summary, identify its type/date, capture a small set of useful fields, let the user verify/correct them, retain the original document, and add the verified event to the timeline.

Afterwards: Add voice AI, adaptive questioning, red-flag detection, smart summaries, AYUSH mode, consent/access controls and ABDM/FHIR integration.

4. Language Plan

Yes — the website can support English, Hindi and Tamil. Use a translation-resource approach so UI labels, buttons, instructions and messages can switch language without changing the underlying patient data. Start with English + Tamil + Hindi; add voice later as a separate module.

5. Simple Medical Document Intelligence

Patient/doctor uploads a prescription, lab report or discharge summary → system records document type/date → captures useful fields such as diagnosis, medicine, investigation and result → user verifies/corrects → original document remains available → verified information becomes a timeline event.

6. Target Flow

Registration → Patient ID + QR → Consultation → Document Upload → Key Information Extraction/Verification → Automatic Timeline → Patient Search/Scan → Doctor reviews the complete journey → later Smart Summary/Handover.

7. Development Rule

Keep one central patient record and make every feature contribute to it. Build the reliable core first, then add advanced AI. Do not reset or delete existing patient data while evolving the application.
